Základní východiska

- Nejvýraznější riziko – cigarety
- **28-32 % populace** ČR – aktivními kuřáky (2011)
- **25 % dětí** (Praha a SČ) 8-12 let – kuřácká zkušenost
- Přídatná rizika (průmysl a doprava)
- Pasivní kouření – zejména dětského věku
- Hranice prokazatelného rizika – 20 balíčkoroků

Sovinová et al 2013
Kucerova et al 2017
Ferrante et al 2017
GOLD 2017

Okénko příležitosti
možnost sekundární prevence

- První detekovatelné patologické změny (CT, zátěžové testy) po **30. roku věku** u časných kuřáků
- Většina nových pacientů má nějaké "dechové obtíže", ale nehledá pomoc a **zůstává nadále** v **rizikové expozici**
- Vývoj CHOPN je **nejrychlejší** ve stadiu **GOLD 2**
- První stanovení diagnózy (CEE) **58 let**
- Průměrný věk (CEE) **66 let**

Background

COPD can be diagnosed early using spirometry, but spirometry use is only recommended in symptomatic smokers, even though early stages of COPD can be asymptomatic. We investigated the prognosis of individuals with asymptomatic and symptomatic, undiagnosed COPD in the general population in Denmark.

Methods

GOLD 2-3-4 20-100 let

In this prospective cohort study, we analysed data from 95 288 individuals aged 20–100 years from the Copenhagen General Population Study. 32 518 (34%) of these individuals were regarded as being at high risk for COPD (defined as individuals aged 40 years or older, with cumulative tobacco consumption of ten pack-years or higher, and without self-reported or a previous hospital contact for asthma). COPD was defined as FEV_1/forced vital capacity (FVC) of less than 70% and less than the lower limit of normal, and FEV_1 of less than 80% of the predicted normal value. Individuals were considered undiagnosed if neither a previous COPD hospital contact, nor medical treatment for COPD, was registered. We obtained information on exacerbations and pneumonia from the National Danish Patient Registry and vital status from the National Danish Civil Registration System, and cause of death from the National Danish Causes of Death Registry. We used Cox proportional hazard models to assess risk of exacerbations, pneumonia, deaths due to respiratory causes, and deaths from all causes from 2003 to 2014.

Findings

GOLD 2-3-4

Between Nov 26, 2003, and July 10, 2013, 95 288 individuals were screened and 32 518 (34%) were at high risk of having COPD. 3699 (11%) of these participants met the COPD criteria and 2903 (78%) were undiagnosed, of whom 2052 (71%) were symptomatic. During a median follow-up of 6·1 years (IQR 4·9), we recorded 800 exacerbations, 2038 cases of pneumonia, and 2789 deaths in the 32 518 individuals at high risk of having COPD, including 152 deaths due to respiratory disease. Compared with individuals without COPD, the age and sex adjusted hazard ratio (HR) was 5·0 (95% CI 2·8–8·9) for exacerbations, 1·7 (1·3–2·2) for pneumonia, 0·7 (0·2–3·0) for death from respiratory causes, and 1·3 (1·1–1·6) for death from all causes in individuals with undiagnosed, asymptomatic COPD. Corresponding HRs were 15·5 (11·0–21·8) for exacerbations, 2·8 (2·4–3·3) for pneumonia, 4·3 (2·8–6·7) for death from respiratory causes, and 2·0 (1·8–2·3) for death from all causes in individuals with undiagnosed, symptomatic COPD.

Interpretation

Individuals with undiagnosed, symptomatic COPD had an increased risk of exacerbations, pneumonia, and death. Individuals with undiagnosed, asymptomatic COPD had an increased risk of exacerbations and pneumonia. These findings suggest that better initiatives for early diagnosis and treatment of COPD are needed.

Targeted case finding for chronic obstructive pulmonary disease versus routine practice in primary care (TargetCOPD): a cluster-randomised controlled trial

Dr Rachel E Jordan, PhD, Prof Peymané Adab, MD, Alice Sitch, MSc, Alexandra Enocson, PhD, Deirdre Blissett, MSc, Sue Jowett, PhD, Jen Marsh, PhD, Prof Richard D Riley, PhD, Prof Martin R Miller, MD, Brendan G Cooper, PhD, Alice M Turner, PhD, Prof Kate Jolly, PhD, Prof Jon G Ayres, MD, Shamil Haroon, PhD, Robert Stockley, DSc, Prof Sheila Greenfield, PhD, Prof Stanley Siebert, PhD, Amanda J Daley, PhD, Prof K K Cheng, FMedSci, Prof David Fitzmaurice, PhD

Background

Many individuals with chronic obstructive pulmonary disease (COPD) remain undiagnosed worldwide. Health-care organisations are implementing case-finding programmes without good evidence of which are the most effective and cost-effective approaches. We assessed the effectiveness and cost-effectiveness of two alternative approaches to targeted case finding for COPD compared with routine practice.

Methods

In this cluster-randomised controlled trial, participating general practices in the West Midlands, UK, were randomly assigned (1:1), via a computer-generated block randomisation sequence, to either a targeted case-finding group or a routine care group. Eligible patients were ever-smokers aged 40–79 years without a previously recorded diagnosis of COPD. Patients in the targeted case-finding group were further randomly assigned (1:1) via their household to receive either a screening questionnaire at the general practitioner (GP) consultation (opportunistic) or a screening questionnaire at the GP consultation plus a mailed questionnaire (active). Respondents reporting relevant respiratory symptoms were invited for post-bronchodilator spirometry. Patients, clinicians, and investigators were not masked to allocation, but group allocation was concealed from the researchers who performed the spirometry assessments. Primary outcomes were the percentage of the eligible population diagnosed with COPD within 1 year (defined as post-bronchodilator forced expiratory volume in 1 s [FEV_1] to forced vital capacity [FVC] ratio <0·7 in patients with symptoms or a new diagnosis on their GP record) and cost per new COPD diagnosis. Multiple logistic and Poisson regression were used to estimate effect sizes. Costs were obtained from the trial. This trial is registered with ISRCTN, number ISRCTN14930255.

GOLD 1-2-3-4
40-79 let

Findings

From Aug 10, 2012, to June 22, 2014, 74 818 eligible patients from 54 diverse general practices were randomly assigned and completed the trial. At 1 year, 1278 (4%) cases of COPD were newly detected in 32 789 eligible patients in the targeted case-finding group compared with 337 (1%) cases in 42 029 patients in the routine care group (adjusted odds ratio [OR] 7·45 [95% CI 4·80–11·55], p<0·0001). The percentage of newly detected COPD cases was higher in the active case-finding group (822 [5%] of 15 378) than in the opportunistic case-finding group (370 [2%] of 15 387; adjusted OR 2·34 [2·06–2·66], p<0·0001; adjusted risk difference 2·9 per 100 patients [95% CI 2·3–3·6], p<0·0001). Active case finding was more cost-effective than opportunistic case finding (£333 *vs* £376 per case detected, respectively).

Interpretation

In this well established primary care system, routine practice identified few new cases of COPD. An active targeted approach to case finding including mailed screening questionnaires before spirometry is a cost-effective way to identify undiagnosed patients and has the potential to improve their health.

Doporučení ACP/ACCP/ATS/ERS 2011

Annals of Internal Medicine®

Recommendation 1: ACP, ACCP, ATS, and ERS recommend that spirometry should be obtained to diagnose airflow obstruction in patients with respiratory symptoms (Grade: strong recommendation, moderate-quality evidence). Spirometry should not be used to screen for airflow obstruction in individuals without respiratory symptoms (Grade: strong recommendation, moderate-quality evidence).

Plán pro rok 2018

- Březen-duben 2018 - kontaktování **14 plicních lékařů**
- Každý plicní lékař (1 na kraj) kontaktuje **cca 3 praktické lékaře**
- **Od září 2018 zahájení projektu**
- PL posílá všechny rizikové osoby
- PNE vyšetřuje všechny rizikové od PL, CHOPN si *"ponechá"*

Práce pro PL

- Prohledat aktivně kartotéku
- Nalézt všechny 45-65 let s anamnézou kouření
- Pokud kouření nad 20 balíčkoroků tak telefonát zda se zadýchají při rychlé chůzi
- Pokud ano, tak jejich nasměrování na PNE

Práce pro PNE

- Všechny co přijdou od PL vyšetřit *(mMRC, CAT a post-BD funkční)*
- Výsledky zhodnotit
- Negativní (*NON-COPD*) poučit o vhodnosti nekouření
- Pozitivním (*new COPD*) nabídnout péči a případně zahájit léčbu adekvátně jejich stavu (GOLD 1 a GOLD 2 budou tvořit většinu)
- Intervence na asociované komorbidity, pohyb, vakcinace,..
